

Novelty of MindBridge AI Over Copewell

#	COPEWELL	MINDBRIDGE AI	WHY THIS IS A NOVELTY
1	Focuses on: language, internet access, and cost. It does not specifically discuss accessibility for people with disabilities.	Focuses on disability accessibility. It supports visual, hearing, speech, motor, and cognitive needs using simpler sentences, captions, voice output, and quick-reply buttons.	MindBridge AI adds disability accessibility as a specific part of mental-health support.
2	Uses extra information such as wearable health data, sleep information, and calendar data.	Uses the user's message itself. It looks at emotion, topic, intensity, duration, and whether the user wants advice or simply wants to talk.	MindBridge AI can work without a smartwatch, health device, or calendar connection.
3	Uses a predefined crisis response to provide consistent safety information.	Keeps the crisis message controlled for safety, but changes how it is delivered — for example, captions, screen-reader support, or reading it aloud.	It makes crisis support more accessible without changing the important safety information.
4	Uses one main Ethics Supervisor for safety rules and crisis detection.	Uses a separate crisis-service to check messages for possible crisis situations.	Separating crisis detection makes it easier to test, monitor, and update.
5	Mainly describes the system as a design concept rather than a set of independently deployable services.	Uses five separate Dockerized services . Each service can be tested, updated, and replaced independently.	This makes MindBridge AI closer to a real deployable application and easier to maintain.
6	Mainly relies on the normal application interface for user input.	Supports voice input using Whisper speech-to-text and a browser Web Speech API fallback.	Users who have difficulty typing can speak instead , improving accessibility for people with motor difficulties.
